

PlatEMO

*Evolutionary Multi-Objective
Optimization Platform*

User Manual 4.5

BIMK Group

December 18, 2023

Thank you very much for using PlatEMO. The copyright of PlatEMO belongs to the BIMK Group of Anhui University, China. This platform is only for research and educational purposes. The codes were implemented based on our understanding of the algorithms published in literatures. You should not rely upon the material or information provided by the platform as a basis for making any business, legal or any other decisions. We assume no responsibilities for any consequences of your using any codes in the platform. All publications using the platform should acknowledge the use of "PlatEMO" and cite one of the following two papers:

[1] Ye Tian, Ran Cheng, Xingyi Zhang, and Yaochu Jin, "PlatEMO: A MATLAB platform for evolutionary multi-objective optimization [educational forum]," IEEE Computational Intelligence Magazine, 2017, 12(4): 73-87.

[2] Ye Tian, Weijian Zhu, Xingyi Zhang, and Yaochu Jin, "A practical tutorial on solving optimization problems via PlatEMO," Neurocomputing, 2023, 518: 190-205.

If you have any comment or suggestion to PlatEMO, please send it to field910921@gmail.com (Dr. Ye Tian). If you want to add your code to PlatEMO, please send the ready-to-use code and the relevant literature to field910921@gmail.com as well. You can obtain the newest version of PlatEMO from GitHub.

I. Quick Start

Requirement: MATLAB R2018a or higher (PlatEMO without GUI) or MATLAB R2020b or higher (PlatEMO with GUI) with Parallel Computing Toolbox and Statistics and Machine Learning Toolbox

PlatEMO is an open-source platform for solving optimization problems, whose input is an optimization problem and output is the found optimal solutions. An optimization problem is defined as

$$\begin{aligned} \min_{\mathbf{x}} \quad & \mathbf{f}(\mathbf{x}) = (f_1(\mathbf{x}), f_2(\mathbf{x}), \dots, f_M(\mathbf{x})) \\ \text{s. t.} \quad & \mathbf{x} = (x_1, x_2, \dots, x_D) \in \Omega \\ & g_1(\mathbf{x}), g_2(\mathbf{x}), \dots, g_K(\mathbf{x}) \leq 0 \end{aligned}$$

where \mathbf{x} denotes a **solution** or **decision vector** for the problem, which consists of D **decision variables** x_i , and each decision variable can be a real number, integer, binary number, or others. Ω denotes the **search space** of the problems, which consists of the **lower bound** l_1, l_2, \dots, l_D and the **upper bound** u_1, u_2, \dots, u_D , i.e., each decision variable should always satisfy that $l_i \leq x_i \leq u_i$. $f_1(\mathbf{x}), f_2(\mathbf{x}), \dots, f_M(\mathbf{x})$ denote the M **objective values** of the solution, and $g_1(\mathbf{x}), g_2(\mathbf{x}), \dots, g_K(\mathbf{x})$ denote the K **constraint violations** of the solution.

To define an optimization problem, users should input at least the following contents:

- The encoding scheme of each decision variable (real, integer, binary, etc.);
- The lower bound l_1, l_2, \dots, l_D and the upper bound u_1, u_2, \dots, u_D ;
- At least one objective function $f_1(\mathbf{x})$.

To define an optimization problem more precisely, users can also input the following contents:

- Multiple objective functions $f_1(\mathbf{x}), f_2(\mathbf{x}), \dots, f_M(\mathbf{x})$;
- Multiple constraint functions $g_1(\mathbf{x}), g_2(\mathbf{x}), \dots, g_K(\mathbf{x})$;
- Function for initializing solutions;
- Function for repairing invalid solutions;
- Function for evaluating solutions;
- Gradient functions of objectives $f'_1(\mathbf{x}), f'_2(\mathbf{x}), \dots, f'_M(\mathbf{x})$;
- Gradient functions of constraints $g'_1(\mathbf{x}), g'_2(\mathbf{x}), \dots, g'_K(\mathbf{x})$;
- Data used in the calculation of all functions (an arbitrary constant).

The above functions are MATLAB functions rather than mathematical functions, which

should have specified inputs and outputs but need not have explicit mathematical expressions. Moreover, users can define the settings of optimization algorithms, to achieve the improvement of optimization performance via selecting suitable algorithms and parameter settings.

In MATLAB, users can call the main file `platemo.m` in the following three ways:

1) Calling the main function with parameters:

```
platemo('problem',@SOP_F1,'algorithm',@GA);
```

Then the specified benchmark problem will be solved by the specified algorithm with specified parameter settings, where the result can be displayed, saved, or returned (see *Solving Benchmark Problems* for details).

2) Calling the main function with parameters:

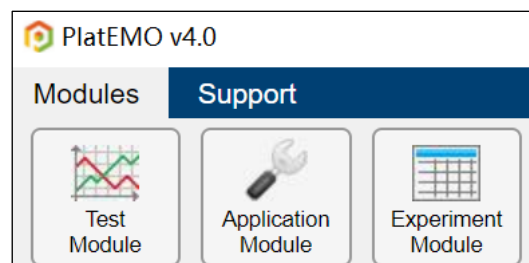

```
f1 = @(x) sum(x);
f2 = @(x) 1-sum(x);
platemo('objFcn',f1,'conFcn',f2,'algorithm',@GA);
```

Then the user-defined problem will be solved by the specified algorithm with specified parameter settings (see *Solving User-Defined Problems* for details).

3) Calling the main function without parameter:

```
platemo();
```

Then a GUI with three modules will be displayed, where the test module is used to visually investigate the performance of an algorithm on a benchmark problem (see *Functions of Test Module* for details), the application module is used to solve user-defined problems (see *Functions of Application Module* for details), and the experiment module is used to statistically analyze the performance of multiple algorithms on multiple benchmark problems (see *Functions of Experiment Module* for details).

II. Using PlatEMO without GUI

A. Solving Benchmark Problems

Users can use PlatEMO without GUI by calling the main function `platemo()` with parameters like

```
platemo('Name1',Value1,'Name2',Value2,'Name3',Value3,...);
```

where all the acceptable names and values are

Name	Data type	Default value	Description
'algorithm'	Function handle or cell	dependent	Class of algorithm
'problem'	Function handle or cell	dependent	Class of problem
'N'	Positive integer	100	Population size
'M'	Positive integer	dependent	Number of objectives
'D'	Positive integer	dependent	Number of variables
'maxFE'	Positive integer	10000	Maximum number of function evaluations
'maxRuntime'	Positive number	inf	Maximum runtime
'save'	Integer	-10	Number of saved populations
'outputFcn'	Function handle	@DefaultOutput	Function called before each iteration Input 1: Class of algorithm Input 2: Class of problem Output: None

- 'algorithm' denotes the algorithm to be run, whose value should be the function handle of an algorithm, such as @GA. The value can also be a cell like {@GA,p1,p2,...}, where p1,p2,... specify the parameter values of the algorithm. For example, the following code solves the default problem via the algorithm @GA with specified parameters:

```
platemo('algorithm',{@GA,1,30,1,30});
```

- 'problem' denotes the benchmark problem to solve, whose value should be the function handle of a benchmark problem, such as @SOP_F1. The value can also be a cell like {@SOP_F1,p1,p2,...}, where p1,p2,... specify the parameter values of the benchmark problem. For example, the following code solves the problem

@WFG1 with specified parameters via the default algorithm:

```
platemo('problem',{@WFG1,20});
```

- 'N' denotes the population size of the algorithm, which usually equals the number of solutions in the final population. For example, the following code solves the problem @SOP_F1 via the algorithm @GA with a population size of 50:

```
platemo('algorithm',@GA,'problem',@SOP_F1,'N',50);
```

- 'M' denotes the number of objectives of the benchmark problem, which is valid for some multi-objective benchmark problems. For example, the following code solves the problem @SOP_F1 via the algorithm @GA with a population size of 50:

```
platemo('algorithm',@GA,'problem',@SOP_F1,'N',50);
```

- 'D' denotes the number of decision variables of the benchmark problem, which is valid for some benchmark problems. For example, the following code solves the problem @SOP_F1 with 100 variables via the algorithm @GA:

```
platemo('algorithm',@GA,'problem',@SOP_F1,'D',100);
```

- 'maxFE' denotes the maximum number of available function evaluations, which usually equals the product of population size and number of generations. For example, the following code sets the maximum number of function evaluations to 20000 for the algorithm:

```
platemo('algorithm',@GA,'problem',@SOP_F1,'maxFE',20000);
```

- 'maxRuntime' denotes the maximum runtime (in second). When 'maxRuntime' equals its default value `inf`, the algorithm will terminate after 'maxFE' function evaluations; otherwise, the algorithm will terminate after 'maxRuntime' seconds. For example, the following code sets the maximum runtime to 10 seconds for the algorithm:

```
platemo('algorithm',@GA,'problem',@SOP_F1,'maxRuntime',10);
```

- 'save' denotes the number of saved populations, where the populations are saved to a file if the value is positive and displayed in a figure if the value is negative (see *Collecting the Results* for details).
- 'outputFcn' denotes the function called before each iteration of the algorithm. An output function has two inputs and no output, where the first input is the current ALGORITHM object and the second input is the current PROBLEM object. The default 'outputFcn' saves or displays the populations according the value of 'save'.

Note that users need not specify all the parameters as each of them has a default value.

B. Solving User-Defined Problems

When the parameter '`problem`' is not specified, users can define their own problem by specifying the following parameters:

Name	Data type	Default value	Description
<code>'objFcn'</code>	Function handle, matrix, or cell	<code>{ }</code>	Objective functions; all the objectives are to be minimized Input: A decision vector Output: Objective value (scalar)
<code>'encoding'</code>	Scalar or row vector	1	Encoding scheme of each variable
<code>'lower'</code>	Scalar or row vector	0	Lower bound of each variable
<code>'upper'</code>	Scalar or row vector	1	Upper bound of each variable
<code>'conFcn'</code>	Function handle, matrix, or cell	<code>{ }</code>	Constraint functions; a constraint is satisfied if and only if the constraint violation is not positive Input: A decision vector Output: Constraint violation (scalar)
<code>'decFcn'</code>	Function handle	<code>{ }</code>	Function for repairing an invalid solution Input: A decision vector Output: Repaired decision vector
<code>'evalFcn'</code>	Function handle	<code>{ }</code>	Function for evaluating a solution Input: A decision vector Output 1: Repaired decision vector Output 2: All objective values (vector) Output 3: All constraint violations (vector)
<code>'initFcn'</code>	Function handle	<code>{ }</code>	Function for initializing a population Input: Population size Output: A matrix consisting of the decision vectors of all solutions
<code>'objGradFcn'</code>	Function handle or cell	<code>{ }</code>	Gradient functions of objectives Input: A decision vector Output: Gradient (vector)
<code>'conGradFcn'</code>	Function handle or cell	<code>{ }</code>	Gradient functions of constraints Input: A decision vector Output: Gradient (vector)
<code>'data'</code>	Any	<code>{ }</code>	Data of the problem

- '`objFcn`' denotes the objective functions of the problem, whose value can be a function handle (a single objective), a matrix (a function is automatically fitted),

or cell (multiple objectives). An objective function has one input and one output, where the input is a decision vector and the output is the objective value. All the objectives are to be minimized. For example, the following code solves a bi-objective optimization problem with six real variables via the default algorithm:

```
f1 = @(x)x(1)+sum(x(2:end));
f2 = @(x)sqrt(1-x(1)^2)+sum(x(2:end));
platemo('objFcn',{f1,f2},'D',6);
```

where the first objective is $x_1 + \sum_{i=2}^D x_i$ and the second objective is $\sqrt{1-x_1^2} + \sum_{i=2}^D x_i$. If an objective function is a matrix, a function will be automatically fitted via Gaussian process regression, where each row of the matrix is a sample and each column of the matrix is a variable (except for the last column) or a function value (the last column). For example, the following code solves the same problem, while the objective functions are automatically fitted:

```
x = rand(50,6);
y1 = x(:,1)+sum(x(:,2:end),2);
y2 = sqrt(1-x(:,1).^2)+sum(x(:,2:end),2);
platemo('objFcn',[x,y1],[x,y2],'D',6);
```

- `'encoding'` denotes the encoding scheme of each variable, whose value can be a scalar or row vector, and the value of each dimension can be 1 (real number), 2 (integer), 3 (label), 4 (binary number), or 5 (permutation number). The algorithms may generate solutions via different strategies for different encoding schemes. For example, the following code specifies three real variables, two integer variables, and one binary variable:

```
f1 = @(x)x(1)+sum(x(2:end));
f2 = @(x)sqrt(1-x(1)^2)+sum(x(2:end));
platemo('objFcn',{f1,f2},'encoding',[1,1,1,2,2,4]);
```

the number of variables D is automatically set to the length of `'encoding'`.

- `'lower'` and `'upper'` denote the lower and upper bound of each variable, respectively, whose values can be scalars or row vectors, and the value of each dimension should be real. `'lower'` and `'upper'` should have the same length as `'encoding'`. For example, the following code specifies a search space $[0,1] \times [0,9]^5$:

```
f1 = @(x)x(1)+sum(x(2:end));
f2 = @(x)sqrt(1-x(1)^2)+sum(x(2:end));
platemo('objFcn',{f1,f2},'encoding',[1,1,1,2,2,4],...
'lower',0,'upper',[1,9,9,9,9,9]);
```

- `'conFcn'` denotes the constraint functions of the problem, whose value can be a function handle (a single constraint), a matrix (a function is automatically fitted), or cell (multiple constraints). A constraint function has one input and one output, where the input is a decision vector and the output is the constraint violation. A constraint is satisfied if and only if the constraint violation is not positive. For example, the following code solves a bi-objective optimization problem via the default algorithm:

```
f1 = @(x)x(1)+sum(x(2:end));
f2 = @(x)sqrt(1-x(1)^2)+sum(x(2:end));
g1 = @(x)1-sum(x(2:end));
platemo('objFcn',{f1,f2},'encoding',[1,1,1,2,2,4],...
'conFcn',g1,'lower',0,'upper',[1,9,9,9,9,9]);
```

and adds a constraint $\sum_{i=2}^6 x_i \geq 1$. Note that equality constraints should be converted into inequality constraints, the details of which can be found in Section 3.2 of *this paper*. If a constraint function is a matrix, a function will be automatically fitted via Gaussian process regression, where each row of the matrix is a sample and each column of the matrix is a variable (except for the last column) or a function value (the last column). For example, the following code solves the same problem, while the constraint function is automatically fitted:

```
f1 = @(x)x(1)+sum(x(2:end));
f2 = @(x)sqrt(1-x(1)^2)+sum(x(2:end));
x = rand(50,6);
y = 1-sum(x(:,2:end),2);
platemo('objFcn',{f1,f2},'encoding',[1,1,1,2,2,4],...
'conFcn',[x,y],'lower',0,'upper',[1,9,9,9,9,9]);
```

- `'decFcn'` denotes the function for repairing an invalid solution, whose value should be a function handle having one input and one output, where the input is a decision vector and the output is the repaired decision vector. For example, the following code makes x_1 always be a multiple of 0.1:

```
f1 = @(x)x(1)+sum(x(2:end));
f2 = @(x)sqrt(1-x(1)^2)+sum(x(2:end));
g1 = @(x)1-sum(x(2:end));
h = @(x)[round(x(1)/0.1)*0.1,x(2:end)];
platemo('objFcn',{f1,f2},'encoding',[1,1,1,2,2,4],...
'conFcn',g1,'decFcn',h,'lower',0,'upper',[1,9,9,9,9,9]);
```

- `'evalFcn'` denotes the function for evaluating a solution, whose value should be a function handle having one input and three output, where the input is a decision vector, the first output is the repaired decision vector, the second output is the

vector of objective values, and the third vector is the vector of constraint violations. The default `'evalFcn'` calls `'decFcn'`, `'objFcn'`, and `'conFcn'` in sequence to evaluate a solution, while the following code defines a new `'evalFcn'` to achieve solution repair, objective calculation, and constraint calculation simultaneously:

```
function [x,f,g] = Eval(x)
    x = [round(x(1)/0.1)*0.1,x(2:end)];
    x = max(0,min([1,9,9,9,9,9],x));
    f(1) = x(1)+sum(x(2:end));
    f(2) = sqrt(1-x(1)^2)+sum(x(2:end));
    g = 1-sum(x(2:end));
end
```

Then, the following codes solve the same problem by specifying only the evaluation function:

```
platemo('evalFcn',@Eval,'encoding',[1,1,1,2,2,4],...
'lower',0,'upper',[1,9,9,9,9,9]);
```

- `'initFcn'` denotes the function for initializing a population, whose value should be a function handle having one input and one output, where the input is the number of solutions in the population and the output is a matrix consisting of the decision vectors in the population. The default `'initFcn'` randomly generates solutions in the whole search space, while the following code defines a new `'initFcn'` to accelerate the convergence:

```
q = @(N)rand(N,6);
platemo('evalFcn',@Eval,'encoding',[1,1,1,2,2,4],...
'initFcn',q,'lower',0,'upper',[1,9,9,9,9,9]);
```

- `'objGradFcn'` and `'conGradFcn'` denote the gradient functions of objectives and constraints, respectively, whose values can be function handles or cells. Each gradient function should have one input and one output, where the input is a decision vector and the output is the gradient. The default gradient function estimates the gradient via finite difference, while the following code defines a new `'objGradFcn'` to accelerate the convergence and ensure the population diversity:

```
fg = @(x)[0,x(2:end)];
platemo('evalFcn',@Eval,'encoding',[1,1,1,2,2,4],...
'objGradFcn',fg,'lower',0,'upper',[1,9,9,9,9,9]);
```

Note that only a few algorithms will use gradient information.

- `'data'` denotes the data of the problem, which can be a constant of any type. If

'data' is specified, all the above functions should have an additional input to receive 'data'. For example, the following code solves a rotated single-objective optimization problem:

```
d = rand(RandStream('mlfg6331_64','Seed',28),10)*2-1;
[d,~] = qr(d);
f1 = @(x,d) sum((x*d-0.5).^2);
platemo('objFcn',f1,'encoding',ones(1,10),'data',d);
```

In addition to the above way for defining a problem, a problem object can be created and solved by specified algorithm objects. For example, the following code solves the problem via the algorithm @GA and the algorithm @DE.

```
d = rand(RandStream('mlfg6331_64','Seed',28),10)*2-1;
[d,~] = qr(d);
f1 = @(x,d) sum((x*d-0.5).^2);
PRO = UserProblem('objFcn',f1,'encoding',ones(1,10),'data',d);
ALG1 = GA();
ALG2 = DE();
ALG1.Solve(PRO);
ALG2.Solve(PRO);
```

C. Collecting the Results

The generated populations can be displayed, saved, or returned after the algorithm terminates. If the main function is called like

```
[Dec,Obj,Con] = platemo(...);
```

Then the final population will be returned, where Dec is a matrix consisting of the decision vectors in the final population, Obj is a matrix consisting of the objective values in the final population, and Con is a matrix consisting of the constraint violations in the final population. If the main function is called like

```
platemo('save',Value,...);
```

Then the generated populations will be displayed in a figure if Value is negative (default), where various plots can be displayed by switching the Data source menu on the figure. While if Value is positive, the generated populations will be saved to a MAT file named as PlatEMO\Data\alg\alg_pro_M_D_run.mat, where alg is the algorithm name, pro is the problem name, M is the number of objectives, D is the number of variables, and run automatically increases from 1 until the file name does not exist. A file saves a cell result consisting of the generated populations and a struct metric consisting of the metric values. The whole optimization process of the

algorithm is divided into `Value` equal intervals, where the first column of `result` stores the number of consumed function evaluations at the last iteration of each interval, the second column of `result` stores the population at the last iteration of each interval, and `metric` stores the metric values of the stored populations. The above are achieved by the default output function `@DefaultOutput`, while users can collect the results in their own ways by specifying the value of `'outputFcn'` to the handle of a user-defined output function.

<pre>result = 6x2 cell array {[1650]} {1x50 SOLUTION} {[3300]} {1x50 SOLUTION} {[5000]} {1x50 SOLUTION} {[6650]} {1x50 SOLUTION} {[8300]} {1x50 SOLUTION} {[10000]} {1x50 SOLUTION}</pre>	<pre>metric = struct with fields: runtime: 0.3317 IGD: [6x1 double]</pre>
--	---

Besides, the metric values can be automatically calculated and saved in the experiment module of the GUI. To calculate the metric values manually, users should load a population, construct a `PROBLEM` object, and call its method `CalMetric`, for example,

```
% Load result before performing the following code
pro = DTLZ2();
pro.CalMetric('IGD', result{end});
```

where `'IGD'` is the name of the calculated metric (see *Metric Function* for details). In particular, IGD and HV are the most popular metrics for multi-objective optimization, whose application scopes and methods for defining reference points can be found in Section 5.3 of *this paper*.

III. Using PlatEMO with GUI

A. Functions of Test Module

Users can use PlatEMO with GUI by calling the main function `platemo()` without parameter like

```
platemo();
```

Then the test module of the GUI will be displayed, which is used to visually investigate the performance of an algorithm on a benchmark problem.

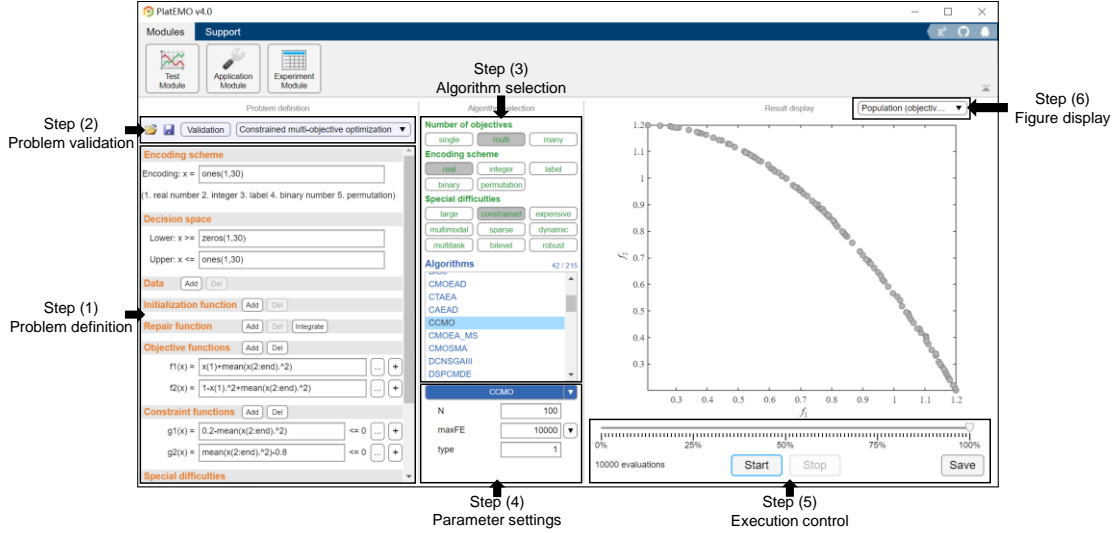

In this module, the performance investigation can be achieved by the following steps:

- Step (1) Select multiple labels to determine the type of problems (see *Labels of Algorithms, Problems, and Metrics* for details).
- Step (2) Select an algorithm from the list.
- Step (3) Select a benchmark problem from the list.
- Step (4) Set the parameters of the algorithm and benchmark problem. Different algorithms and benchmark problems may have different parameters, the details of which can be obtained by hovering over each parameter.
- Step (5) Start, pause, stop, or back off the current execution; save the current result to a file. The current result can be saved as a matrix with N rows and $D + M + K$ columns, where N denotes the number of solutions, D denotes the number of variables, M denotes the number of objectives, and K denotes the number of constraints.
- Step (6) Select a data to display, such as the objective values, variables, and metric values of the current population.
- Step (7) Select a historical result to display.

B. Functions of Application Module

Users can press the menu button to switch to the application module, which is used to solve user-defined problems.

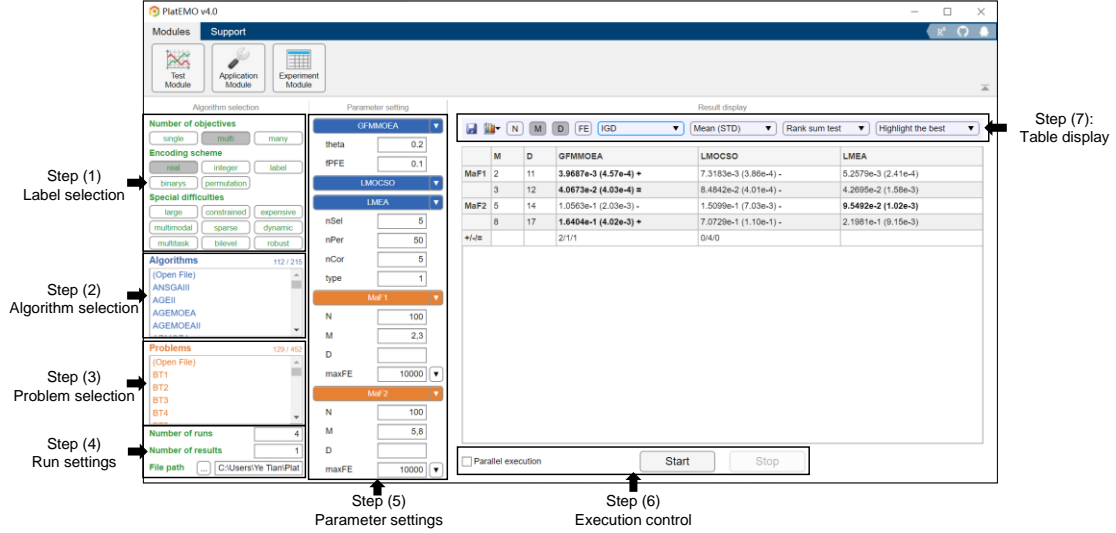

In this module, the solving of problems can be achieved by the following steps:

- Step (1) Define a problem, the contents of which are the same as those in *Solving User-Defined Problems*, where **Encoding scheme** corresponds to 'encoding', **Decision space** corresponds to 'lower' and 'upper', **Data** corresponds to 'data', **Initialization function** corresponds to 'initFcn', **Repair function** corresponds to 'decFcn', **Objective functions** corresponds to 'objFcn', **Constraint functions** corresponds to 'conFcn', and **Evaluation function** corresponds to 'evalFcn'.
- Step (2) Save or load a problem; check the validity of the problem; select a problem template. The saved problem can be opened and solved in other modules.
- Step (3) Select an algorithm from the list. The labels are automatically determined according to the problem definition (see *Labels of Algorithms, Problems, and Metrics* for details).
- Step (4) Set the parameters of the algorithm. Different algorithms may have different parameters, the details of which can be obtained by hovering over each parameter.
- Step (5) Start, pause, stop, or back off the current execution; save the current result to a file. The current result can be saved as a matrix with N rows and $D + M + K$ columns, where N denotes the number of solutions, D denotes the number of variables, M denotes the number of objectives, and K denotes the number of constraints.
- Step (6) Select a data to display, such as the objective values, variables, and metric values of the current population.

C. Functions of Experiment Module

Users can press the menu button to switch to the experiment module, which is used to statistically analyze the performance of multiple algorithms on multiple problems.

In this module, comparative experiments can be achieved by the following steps:

- Step (1) Select multiple labels to determine the type of problems (see *Labels of Algorithms, Problems, and Metrics* for details).
- Step (2) Select multiple algorithms from the list.
- Step (3) Select multiple benchmark problems from the list.
- Step (4) Set the number of repeated runs, number of saved populations in each run, and path for saving results (see *Collecting the Results* for details).
- Step (5) Set the parameters of the algorithms and benchmark problems. Different algorithms and benchmark problems may have different parameters, the details of which can be obtained by hovering over each parameter.
- Step (6) Start or stop the experiment; perform multiple runs in sequence (on a single CPU) or in parallel (on all CPUs).
- Step (7) Select a metric; select a statistical method; save the table to a file; display the results of the selected cells in a figure.

D. Labels of Algorithms, Problems, and Metrics

Each algorithm, benchmark problem, and metric should be tagged with labels by the comment in the second line of its main function. For example, in the code of `PSO.m`:

```
classdef PSO < ALGORITHM
% <single> <real/integer> <large/none> <constrained/none>
```

which indicates the types of problems the algorithm can solve. All the labels are

Label	Description
<single>	Single-objective optimization: The problem has a single objective
<multi>	Multi-objective optimization: The problem has two or three objectives
<many>	Many-objective optimization: The problem has four or more objectives
<real>	Continuous optimization: The decision variables are real numbers
<integer>	Integer optimization: The decision variables are integers
<label>	Label optimization: The decision variables are labels
<binary>	Binary optimization: The decision variables are binary numbers
<permutation>	Permutation optimization: All decision variables constitute a permutation
<large>	Large-scale optimization: The problem has 100 or more variables
<constrained>	Constrained optimization: The problem has at least one constraint
<expensive>	Expensive optimization: The objectives are computationally expensive, only a limited number of function evaluations are available
<multimodal>	Multimodal optimization: There exist multiple optimal solutions with similar objective values but considerably different decision vectors, all of which should be found
<sparse>	Sparse optimization: Most variables of the optimal solutions are zero
<dynamic>	Dynamic optimization: The objectives and constraints vary over time
<multitask>	Multitasking optimization: Optimize multiple problems simultaneously, each problem may have multiple objectives and constraints
<bilevel>	Bilevel optimization: Find the feasible and optimal solution for the upper-level problem, where a solution is feasible for the upper-level problem if and only if it is optimal for the lower-level problem
<robust>	Robust optimization: The objectives and constraints are affected by noise, the robust and optimal solutions should be found
<none>	Empty label
<min>	(for metrics only) The metric value is the smaller the better
<max>	(for metrics only) The metric value is the larger the better

An algorithm may have multiple sets of labels, where the Cartesian product between all the label sets constitutes all the types of problems that can be solved by the algorithm. If the label sets of an algorithm are <single> <real> <constrained/none>, it will be able to solve single-objective continuous optimization problems with or without constraints. On the other hand, the label sets <single> <real> mean that the algorithm can only solve unconstrained problems, the label sets <single> <real> <constrained> mean that the algorithm can only solve constrained problems, and the label sets <single> <real/binary> mean that the algorithm can solve problems with either real variables or binary variables.

Each algorithm, benchmark problem, and metric should be tagged with at least one

label, otherwise it will not be appeared in the lists in the GUI. After selecting multiple labels in the GUI, only the algorithms, benchmark problems, and metrics containing the same labels will be appeared. Details of the label based filter strategy can be found *here*. The labels of all the algorithms and benchmark problems in PlatEMO are referred to *List of Algorithms* and *List of Problems*, respectively.

IV. Extending PlatEMO

A. *ALGORITHM* Class

An algorithm should be written as a subclass of `ALGORITHM` and put in the folder `PlatEMO\Algorithms`, which contains the following properties and methods:

Property	Specified by	Description
<code>parameter</code>	Users	Parameters of the algorithm
<code>save</code>	Users	Number of populations saved in an execution
<code>outputFcn</code>	Users	Function called in <code>NotTerminated()</code>
<code>pro</code>	<code>Solve()</code>	Problem solved in current execution
<code>result</code>	<code>NotTerminated()</code>	Populations saved in current execution
<code>metric</code>	<code>NotTerminated()</code>	Metric values of saved populations
<code>starttime</code>	<code>NotTerminated()</code>	Used for runtime recording
Method	Be redefined	Description
<code>ALGORITHM</code>	Cannot	Set the properties specified by users Input: Parameter settings like ' <code>Name</code> ', <code>Value</code> , ... Output: <code>ALGORITHM</code> object
<code>Solve</code>	Cannot	Solve a problem via the algorithm Input: <code>PROBLEM</code> object Output: None
<code>main</code>	Must	Main procedure of the algorithm Input: <code>PROBLEM</code> object Output: None
<code>NotTerminated</code>	Cannot	Function called before each iteration in <code>main()</code> Input: An array of <code>SOLUTION</code> objects, i.e., a population Output: Whether the algorithm terminates (logical)
<code>ParameterSet</code>	Cannot	Set the parameter values according to <code>parameter</code> Input: Default parameter settings Output: User-specified parameter settings

Each algorithm should inherit `ALGORITHM` and redefine the method `main()`. For example, the code of `GA.m` is

```

1 classdef GA < ALGORITHM
2 % <single><real/integer/label/binary/permutation><large/none><constrained/none>
3 % Genetic algorithm
4 % proC --- 1 --- Probability of crossover
5 % disC --- 20 --- Distribution index of crossover

```

```

6 % proM --- 1 --- Expectation of the number of mutated variables
7 % disM --- 20 --- Distribution index of mutation
8

14     methods
15         function main(Alg,Pro)
16             [proC,disC,proM,disM] = Alg.ParameterSet(1,20,1,20);
17             P = Pro.Initialization();
18             while Alg.NotTerminated(P)
19                 Q = TournamentSelection(2,Pro.N,FitnessSingle(P));
20                 O = OperatorGA(P(Q),{proC,disC,proM,disM});
21                 P = [P,O];
22                 [~,rank] = sort(FitnessSingle(P));
23                 P = P(rank(1:Pro.N));
24             end
25         end
26     end
27 end

```

The functions of each line are as follows:

- Line 1: Inheriting the ALGORITHM class;
- Line 2: Tagging the algorithm with labels (see *Labels of Algorithms, Problems, and Metrics* for details);
- Line 3: Full name of the algorithm;
- Lines 4-7: Parameter name --- default value --- description, which are shown in the parameter setting list in the GUI;
- Lines 9-12: Reference of the algorithm;
- Line 15: Redefining the method of main procedure;
- Line 16: Obtaining the parameter values specified by users, where 1, 20, 1, 20 are default values of the four parameters proC, disC, proM, disM;
- Line 17: Obtaining an initial population by calling a method of the problem;
- Line 18: Storing the population and checking whether the algorithm terminates; if so, the algorithm will immediately terminate by throwing an error;
- Line 19: Binary tournament based mating selection achieved by a public function;
- Line 20: Offspring generation achieved by a public function;
- Line 21: Combining the current population with the offspring population;
- Line 22: Sorting the solutions based on their fitness calculated by a public function;
- Line 23: Retaining half the solutions with better fitness for the next iteration.

In the above codes, the functions `ParameterSet()` and `NotTerminated()` are provided by the `ALGORITHM` class, and the function `Initialization()` is provided by the `PROBLEM` class. Besides, the functions `TournamentSelection()`, `FitnessSingle()`, and `OperatorGA()` are public functions in the folder `PlatEMO\Algorithms\Utility` functions. The following table lists the functions that can be used in algorithms, where the details of them are referred to the comments in their codes. Besides, their techniques for efficiency improvement can be found *here*.

Function Name	Description
ALGORITHM. NotTerminated	Function called before each iteration of the algorithm, which stores the current population and check whether the algorithm terminates
ALGORITHM. ParameterSet	Set the parameter values specified by users
PROBLEM. Initialization	Initialize a population for the problem
PROBLEM. Evaluation	Evaluate a population and generate an array of SOLUTION object
CrowdingDistance	Crowding distance calculation for multi-objective optimization
FitnessSingle	Fitness calculation for single-objective optimization
NDSort	Non-dominated sorting for multi-objective optimization
OperatorDE	The variation operator of differential evolution
OperatorFEP	The variation operator of fast evolutionary programming
OperatorGA	The variation operators of genetic algorithm
OperatorGAhalf	The variation operators of genetic algorithm, where only the first half of offspring solutions are returned
OperatorPSO	The variation operator of particle swarm optimization
RouletteWheel Selection	Roulette-wheel selection
Tournament Selection	Tournament selection
UniformPoint	Generate a set of uniformly distributed points

B. PROBLEM Class

A problem should be written as a subclass of `PROBLEM` and put in the folder `PlatEMO\Problems`, which contains the following properties and methods:

Property	Specified by	Description
N	Users	Population size of algorithms
M	Users and Setting()	Number of objectives of the problem
D	Users and Setting()	Number of decision variables of the problem

maxFE	Users	Maximum number of function evaluations
FE	Evaluation()	Number of function evaluations consumed in current execution
maxRuntime	Users	Maximum runtime
encoding	Setting()	Encoding scheme of each variable
lower	Setting()	Lower bound of each variable
upper	Setting()	Upper bound of each variable
optimum	GetOptimum()	Optimal values of the problem, such as the minimum objective value of single-objective optimization problems and a set of points on the Pareto front of multi-objective optimization problems
PF	GetPF()	Pareto front of the problem, such as a 1-D curve of bi-objective optimization problems, a 2-D surface of tri-objective optimization problems, and feasible regions of constrained optimization problems
parameter	Users	Parameters of the problem
Method	Be redefined	Description
PROBLEM	Cannot	Set the properties specified by users Input: Parameter settings like 'Name', Value, ... Output: ALGORITHM object
Setting	Must	Default settings of the problem Input: None Output: None
Initialization	Can	Initialize a population Input: Population size Output: An array of SOLUTION objects, i.e., a population
Evaluation	Can	Evaluate a population and generate solution objects Input: A matrix consisting of decision vectors Output: An array of SOLUTION objects, i.e., a population
CalDec	Can	Repair invalid solutions in a population Input: A matrix consisting of decision vectors Output: A matrix consisting of repaired decision vectors
CalObj	Must	Calculate the objective values of solutions in a population. All objectives are to be minimized Input: A matrix consisting of decision vectors Output: A matrix consisting of objective values
CalCon	Can	Calculate the constraint violations of solutions in a population. A constraint is satisfied if and only if the constraint violation is not positive Input: A matrix consisting of decision vectors Output: A matrix consisting of constraint violations
CalObjGrad	Can	Calculate the gradients of a solution on objectives

		Input: A decision vector Output: A Jacobian matrix
CalConGrad	Can	Calculate the gradients of a solution on constraints Input: A decision vector Output: A Jacobian matrix
GetOptimum	Can	Generate the optimal values and store in optimum Input: The number of optimal values Output: Optimal values (a matrix)
GetPF	Can	Generate the Pareto front and store in PF Input: None Output: Data for plotting the Pareto front (a matrix or cell)
CalMetric	Can	Calculate the metric value of a population Input 1: Metric name Input 2: An array of SOLUTION objects, i.e., a population Output: Metric value (scalar)
DrawDec	Can	Display the decision variables of a population Input: An array of SOLUTION objects, i.e., a population Output: None
DrawObj	Can	Display the objective values of a population Input: An array of SOLUTION objects, i.e., a population Output: None
ParameterSet	Cannot	Set the parameter values according to parameter Input: Default parameter settings Output: User-specified parameter settings

Each benchmark problem should inherit `PROBLEM` and redefine the methods `Setting()` and `CalObj()`. For example, the code of `SOP_F1.m` is

```

1  classdef SOP_F1 < PROBLEM
2  % <single><real><expensive/none>
3  % Sphere function
4
5  %----- Reference -----
6  % X. Yao, Y. Liu, and G. Lin, Evolutionary programming made
7  % faster, IEEE Transactions on Evolutionary Computation,
8  % 1999, 3(2): 82-102.
9  %-----
10
11  methods
12      function Setting(obj)
13          obj.M = 1;
14          if isempty(obj.D); obj.D = 30; end
15          obj.lower = zeros(1,obj.D) - 100;

```

```

16         obj.upper = zeros(1,obj.D) + 100;
17         obj.encoding = ones(1,obj.D);
18     end
19     function PopObj = CalObj(obj,PopDec)
20         PopObj = sum(PopDec.^2,2);
21     end
22 end
23 end

```

The functions of each line are as follows:

- Line 1: Inheriting the `PROBLEM` class;
- Line 2: Tagging the problem with labels (see *Labels of Algorithms, Problems, and Metrics* for details);
- Line 3: Full name of the problem;
- Lines 5-9: Reference of the problem;
- Line 12: Redefining the method of default parameter settings;
- Line 13: Setting the number of objectives;
- Line 14: Setting the number of decision variables if it is not specified by users;
- Lines 15-16: Setting the lower bounds and upper bounds of decision variables;
- Line 17: Setting the encoding schemes of decision variables;
- Line 19: Redefining the method of calculating objective values;
- Line 20: Calculating the objective values of solutions in a population.

The default method `Initialization()` randomly initializes a population. This method can be redefined to specify a novel initialization strategy. For example, `Sparse_NN.m` initializes a population in which half the decision variables are zero:

```

function Population = Initialization(obj,N)
    if nargin < 2; N = obj.N; end
    PopDec = (rand(N,obj.D)-0.5)*2.*randi([0 1],N,obj.D);
    Population = SOLUTION(PopDec);
end

```

The default method `CalDec()` repairs invalid solutions in a population, where each decision variable will be set to the boundary values if it is larger than the upper bound or smaller than the lower bound. This method can be redefined to specify a novel repair strategy. For example, `MOKP.m` repairs solutions that exceed the capacity, so that no constraint needs to be defined in this problem:

```

function PopDec = CalDec(obj,PopDec)
    C = sum(obj.W,2)/2;
    [~,rank] = sort(max(obj.P./obj.W));
    for i = 1 : size(PopDec,1)

```

```
while any(obj.W*PopDec(i,:) '>C')
    k = find(PopDec(i,rank),1);
    PopDec(i,rank(k)) = 0;
end
end
end
```

The default method `CalCon()` returns zero as the constraint violation of the solutions in a population, i.e., all the solutions are feasible. This method can be redefined to specify constraint functions for the problem. For example, `CF4.m` calculates a constraint for each solution:

```
function PopCon = CalCon(obj,X)
    t = X(:,2)-sin(6*pi*X(:,1)+2*pi/size(X,2))-0.5*X(:,1)+0.25;
    PopCon = -t./(1+exp(4*abs(t)));
end
```

Use `all(PopCon<=0,2)` to determine whether each solution is feasible or not. Note that equality constraints should be converted into inequality constraints, the details of which can be found in Section 3.2 of *this paper*. The default method `Evaluation()` calls `CalDec()`, `CalObj()`, and `CalCon()` in sequence to instantiate `SOLUTION` objects, and also adds the number of consumed function evaluations `FE`. This method can be redefined to perform solution repair, objective calculation, and constraint calculation in a single function, where `CalDec()`, `CalObj()`, and `CalCon()` will not be called anymore. For example, `MW2.m` calculates objective values and constraint violations in a single function:

```
function Population = Evaluation(obj,varargin)
    X = varargin{1};
    X=max(min(X, repmat(obj.upper, size(X,1),1)), repmat(obj.lower, size(X,1),1));
    z=1-exp(-10*(X(:,obj.M:end)-(repmat(obj.M:obj.D, size(X,1),1)-1)/obj.D).^2);
    g = 1+sum((1.5+(0.1/obj.D)*z.^2-1.5*cos(2*pi*z)),2);
    PopObj(:,1) = X(:,1);
    PopObj(:,2) = g.*(1-PopObj(:,1)./g);
    L = sqrt(2)*PopObj(:,2)-sqrt(2)*PopObj(:,1);
    PopCon = sum(PopObj,2)-1-0.5*sin(3*pi*L).^8;
    Population = SOLUTION(X, PopObj, PopCon, varargin{2:end});
    obj.FE = obj.FE+length(Population);
end
```

The default method `CalObjGrad()` estimates the gradients of objectives via finite difference, while this method can be redefined to calculate gradients more accurately. Similarly, the default method `CalConGrad()` estimates the gradients of constraints via finite difference, while this method can be redefined to calculate gradients more

accurately. The method `GetOptimum()` can be redefined to specify the optimal values of the problem, which are used for metric calculation. For example, `SOP_F8.m` returns the optimal value of the objective function:

```
function R = GetOptimum(obj,N)
    R = -418.9829*obj.D;
end
```

and `DTLZ2.m` returns a set of uniformly distributed points on the Pareto front:

```
function R = GetOptimum(obj,N)
    R = UniformPoint(N,obj.M);
    R = R./repmat(sqrt(sum(R.^2,2)),1,obj.M);
end
```

The strategies for sampling points on different Pareto fronts can be found *here*. The method `GetPF()` can be redefined to specify the Pareto front or feasible regions of multi-objective optimization problems for the visualization achieved in `DrawObj()`. For example, `DTLZ2.m` returns the data for plotting the 2-D and 3-D Pareto fronts:

```
function R = GetPF(obj)
    if obj.M == 2
        R = obj.GetOptimum(100);
    elseif obj.M == 3
        a = linspace(0,pi/2,10)';
        R = {sin(a)*cos(a'), sin(a)*sin(a'), cos(a)*ones(size(a'))};
    else
        R = [];
    end
end
```

and `MW1.m` returns the data for plotting the feasible regions:

```
function R = GetPF(obj)
    [x,y] = meshgrid(linspace(0,1,400),linspace(0,1.5,400));
    z = nan(size(x));
    fes = x+y-1-0.5*sin(2*pi*(sqrt(2)*y-sqrt(2)*x)).^8 <= 0;
    z(fes&0.85*x+y>=1) = 0;
    R = {x,y,z};
end
```

The default method `CalMetric()` feeds a population and the optimal values `optimum` to a metric function to calculate the metric value. This method can be redefined to feed different variables to metric functions. For example, `SMMOP1.m` feeds the Pareto optimal set rather than the points on the Pareto front when calculating the metric value

of IGDx:

```
function score = CalMetric(obj,metName,Population)
    switch metName
        case 'IGDX'
            score = feval(metName,Population,obj.POS);
        otherwise
            score = feval(metName,Population,obj.optimum);
    end
end
```

The method `DrawDec()` displays the decision variables of a population, which is used for the visualization of results in the GUI. This method can be redefined to specify a novel visualization method. For example, `TSP.m` displays the route of the best solution:

```
function DrawDec(obj,P)
    [~,best] = min(P.objs);
    Draw(obj.R(P(best).dec([1:end,1]),:),'-k','LineWidth',1.5);
    Draw(obj.R);
end
```

The method `DrawObj()` displays the objective values of a population, which is used for the visualization of results in the GUI. This method can be redefined to specify a novel visualization method. For example, `Sparse_CD.m` adds labels to the axes:

```
function DrawObj(obj,P)
    Draw(P.objs,{ 'Kernel k-means', 'Ratio cut', [] });
end
```

where `Draw()` is a function in the folder `PlatEMO\GUI` for displaying data.

C. SOLUTION Class

A `SOLUTION` object denotes an individual, and an array of `SOLUTION` objects denote a population. The `SOLUTION` class contains the following properties and methods:

Property	Specified by	Description
<code>dec</code>	Users	Decision variables of the solution
<code>obj</code>	<code>SOLUTION()</code>	Objective values of the solution
<code>con</code>	<code>SOLUTION()</code>	Constraint violations of the solution
<code>add</code>	<code>adds()</code>	Additional properties (e.g., velocity) of the solution
Method		Description
<code>SOLUTION</code>	Generate <code>SOLUTION</code> objects Input 1: A matrix consisting of decision vectors Input 2: A matrix consisting of objective values	

	Input 3: A matrix consisting of constraint violations Input 4: A matrix consisting of additional properties Output: An array of SOLUTION objects
decs	Get the decision variables of multiple solutions Input: None Output: A matrix consisting of decision vectors
objs	Get the objective values of multiple solutions Input: None Output: A matrix consisting of objective values
cons	Get the constraint violations of multiple solutions Input: None Output: A matrix consisting of constraint violations
adds	Set and get the additional properties of multiple solutions Input: Default additional properties Output: A matrix consisting of additional properties
best	Get the feasible and best solution for single-objective optimization, or the feasible and non-dominated solutions for multi-objective optimization Input: None Output: A subarray of best SOLUTION objects in the population

For example, the following code generates a population with ten solutions, then gets the objective matrix of the best solutions in the population:

```
Population = SOLUTION(rand(10,5),rand(10,1),zeros(10,1));
BestObjs   = Population.best.objs
```

Note that SOLUTION() should be called only in the method Evaluation() of PROBLEM class.

D. Whole Procedure of One Run

The following code uses the genetic algorithm to solve the sphere function:

```
Alg = GA();
Pro = SOP_F1();
Alg.Solve(Pro);
```

where the functions called in the execution of Alg.Solve(Pro) are as follows.

E. Metric Function

A metric should be written as a function and put in the folder PlatEMO\Metrics. For example, the code of IGD.m is

```

1 function score = IGD(Population, optimum)
2 % <min> <multi/many> <real/integer/label/binary/permutation>
3 % <large> <constrained> <expensive>
4 % <multimodal> <sparse> <dynamic> <robust>
5 % Inverted generational distance
6 %----- Reference -----
7 % C. A. Coello Coello and N. C. Cortes, Solving
8 % multiobjective optimization problem using an artificial
9 % immune system, Genetic Programming and Evolvable

```

```

9 % Machines, 2005, 6(2): 163-190.
10 %-----
11
12     PopObj = Population.best.objs;
13     if size(PopObj,2) ~= size(optimum,2)
14         score = nan;
15     else
16         score = mean(min(pdist2(optimum, PopObj), [], 2));
17     end
18 end

```

The functions of each line are as follows:

- Line 1: Function declaration, where the first input is a population (i.e., an array of SOLUTION objects), the second input is the optimums of a problem (i.e., the optimum property of the problem), and the output is the metric value;
- Line 2: Tagging the metric with labels (see *Labels of Algorithms, Problems, and Metrics* for details); note that <min> or <max> should be the first label;
- Line 3: Full name of the metric;
- Lines 5-10: Reference of the metric;
- Line 12: Obtaining the feasible and non-dominated solutions in the population;
- Lines 13-14: Returns nan if there is no feasible solution in the population;
- Lines 15-16: Returns the IGD value of the feasible and non-dominated solutions.

V. List of Algorithms
